Banker's Deadlock Avoidance Algorithm

Completed

Write a C program to implement the Banker's Deadlock Avoidance Algorithm. The program should accept the number of processes and resource types, the Maximum Demand matrix, the currently Allocated resources matrix, and the Available resources vector. Calculate the 'Need' matrix and determine if the system is in a 'Safe State'. If it is safe, display the Safe Sequence; otherwise, indicate that a deadlock may occur.

Input Format

1. The first line of input contains an integer representing the number of processes.
2. The second line contains an integer representing the number of resource types.
3. The next lines contain the Allocation matrix, where each row corresponds to a process and each column corresponds to

Select Language : C (GCC 9.2.0)

```

1 #include <stdio.h>
2
3 int main()
4 {
5     int n, r, i, j, k;
6
7     printf("Enter number of processes: \n");
8     scanf("%d", &n);
9
10    printf("Enter number of resource types: \n");
11    scanf("%d", &r);
12
13    int alloc[n][r], max[n][r], need[n][r];
14    int avail[r], finish[n], safe_seq[n];
15
16    // Input Allocation matrix
17    printf("Enter Allocation Matrix:\n");

```
